# Dynamical Downscaling Types

from *Castro et al. (2005)*

## Examples

**TYPE 1: remembers real-world conditions through the initial and lateral boundary conditions**

Numerical  
weather  
prediction

**TYPE 2: initial conditions in the interior of the model are “forgotten” but the lateral boundary conditions feed real-world data into the regional model**

Retrospective  
sensitivity or process  
studies using global  
reanalyses

**TYPE 3: global model prediction is used to create lateral boundary conditions. The global model prediction includes real-world surface data**

Seasonal  
climate  
forecasting

**TYPE 4: Global model run with no prescribed internal forcings. Couplings among the ocean-land-continental ice-atmosphere are all predicted**

Climate  
change  
projection

## **Definition of RCM:**

**Initial conditions in the interior of the model are “forgotten” but the lateral boundary conditions feed data into the regional model**

***Type 2 dynamical downscaling and above***

# **Some a priori expectations for RCM dynamical downscaling (Type 2 and above)**

## **A RCM should:**

- 1. Retain or enhance variability of larger-scale features provided by the driving global model (i.e. those on the synoptic scale)**
- 2. Add information on the smaller scale because of increase in grid spacing, finer spatial scale data (e.g. terrain, landscape) and possibly differences in model parameterized physics.**
- 3. Add information that is actually of value, as demonstrated by comparing RCM results with independent metrics (e.g. observations for Type 2)**

## RAMS

## CLM

# Quantitative analysis of value retained by RCM at large scales

Compute 2-D power spectrum for a given model variable as a function of wavelength (Errico 1985). Do for both RCM and driving reanalysis.

Appropriate variable for large-scale: kinetic energy

Average power spectra of last 15 days of simulation.

Compute the ratio of average of the power spectra of RCM vs. driving reanalysis.

**Desired: RCM retains or adds value at the largest scales where the driving GCM or reanalysis has information.**

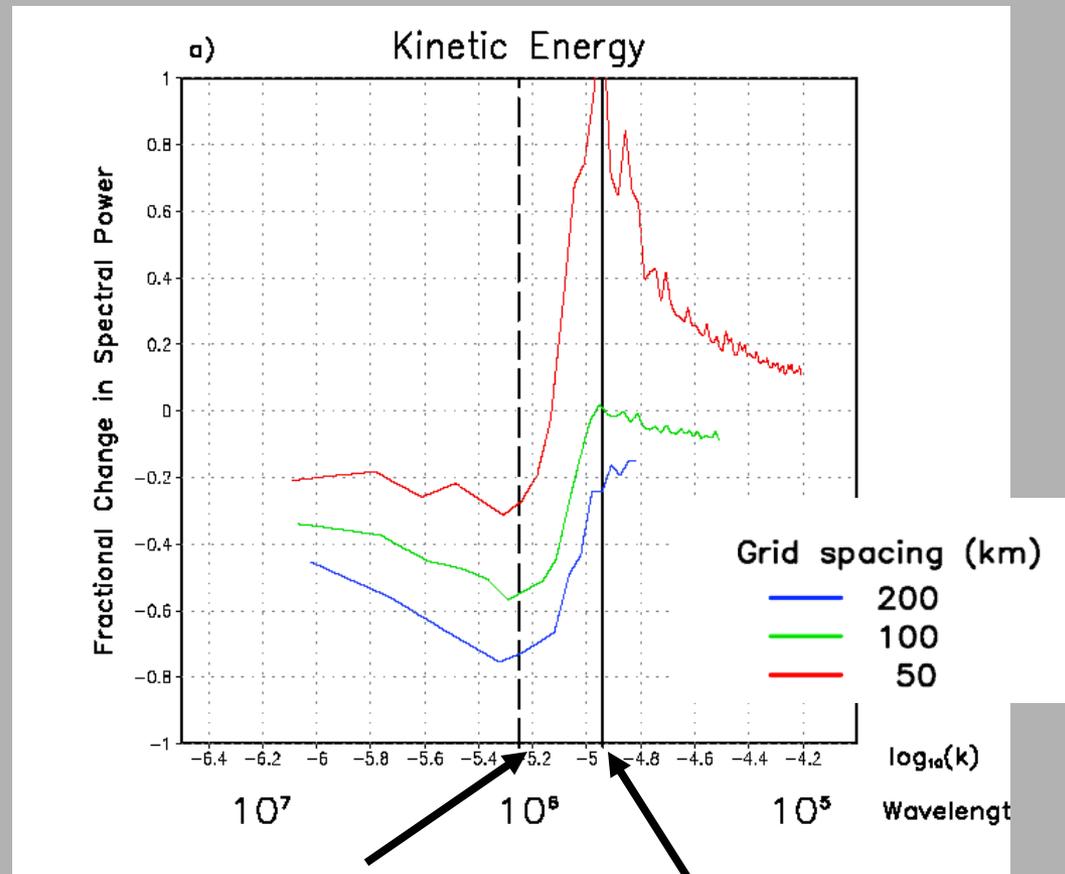

**Undesired: RCM loses variability at the largest scales provided by the driving GCM or reanalysis.**

# Fractional change in spectral power of kinetic energy: RAMS Model

RCM variability  
MORE than driving  
reanalysis.  
VALUE RETAINED  
OR ADDED

RCM variability  
LESS than driving  
reanalysis.  
VALUE LOST

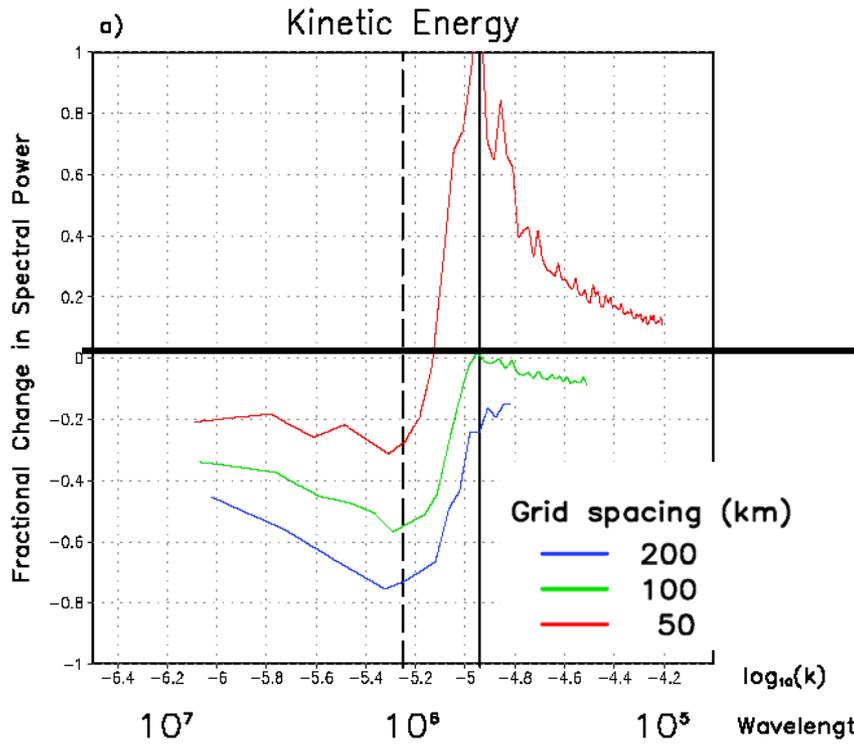

Shortest physically resolved  
wavelength in reanalysis ( $4\Delta x$ )

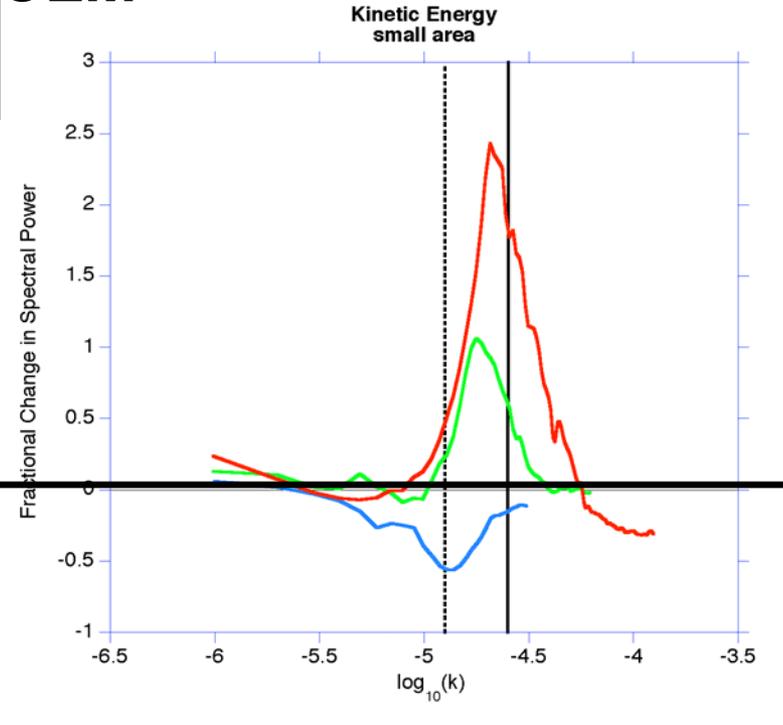

Nyquist frequency of  
reanalysis ( $2\Delta x$ )

# Is the same behavior present in CLM?

**Even greater loss of large-scale variability with a larger domain. RAMS generates identical result.**

# Quantitative analysis of value added by RCM at small scales

Compute 2-D power spectrum for a given model variable as a function of wavelength (Errico 1985). Do for RCM with and without interior nudging.  
Appropriate variable for small-scale: moisture flux convergence

Average power spectra of last 15 days of simulation.

Compute the ratio of average of the power spectra of RCM with interior nudging vs. RCM with no interior nudging.

RAMS: Interior nudging at all wavelengths

CLM: Spectral nudging for largest wavelengths only

**Desired: Interior nudging does not reduce variability at the smaller scales where the RCM is adding information.**

**Undesired: Interior nudging reduces variability at the smaller scales.**

# CLM Spectral nudging in brief

*Applied at scales greater than  $4\Delta x$   
of driving global reanalysis for horizontal winds*

Form of nudging coefficients for a given model variable in spectral domain:

$$\sum_{j=-J_a, k=-K_a}^{J_a, K_a} \eta_{j,k} \left( \alpha_{j,k}^a(t) - \alpha_{j,k}^m(t) \right) e^{ij\lambda/L_\lambda} e^{ik\phi/L_\phi}$$

$$\alpha_{j,k}^a(t)$$

Fourier expansion coefficients of variable in driving larger-scale model (*a*)

$$\alpha_{j,k}^m(t)$$

Fourier expansion coefficients of variable in the regional model (*m*)

$$\eta_{j,k}$$

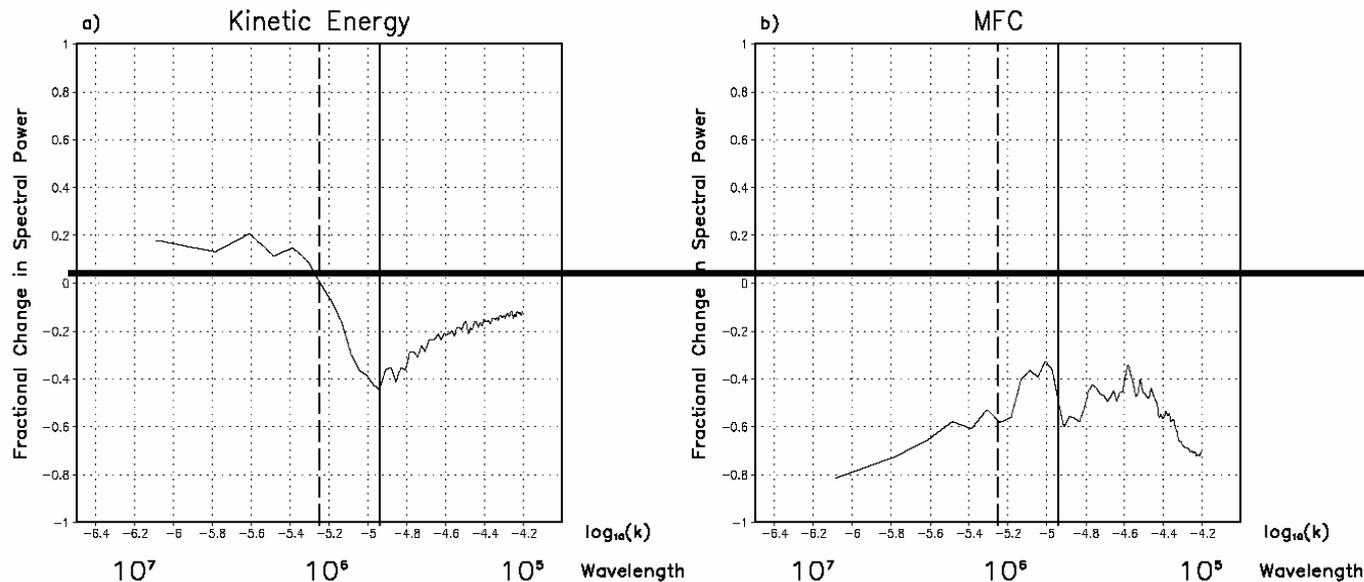

Nudging coefficient. Larger with increasing height.

# Conclusions of our RCM studies

- The results for CLM reported in *Rockel et al. (2008)* are similar to those found in the RAMS study by *Castro et al. (2005)* for basic experiments using nudging only in a lateral boundary sponge zone. In both models, there is a loss of large-scale variability with increasing domain size and grid spacing.
- Internal nudging can alleviate loss of large-scale variability in both RCMs.
- Spectral nudging yields less reduction in added variability of the smaller scales than grid nudging and is therefore the preferred approach in RCM dynamic downscaling.
- Results suggest the effect to be largest for physical quantities in the lower troposphere (e.g. moisture flux convergence, rainfall)

# General conclusions on utility of RCMs

- The utility of all regional models in downscaling primarily is not to add increased skill to the large-scale in the upper atmosphere, rather the value added is to resolve the smaller-scale features which have a greater dependence on the surface boundary.
- However, the realism of these smaller-scale features needs to be quantified, since they will be altered to the extent that they are influenced by inaccurate downscaling of the larger-scale features through the lateral boundary conditions and interior nudging or lack thereof.
- It should also be assessed if the dynamically downscaled information provides more accuracy than a corresponding statistical downscaling technique.
